Dear Editors,

I am submitting for your consideration the manuscript entitled “*The Discrete Frequency Divider: Connecting Proton Compton Oscillation to the 136.1 Hz Carrier Wave via the Icosahedral 60R-Grid.*”

This work establishes a novel mathematical connection between the proton Compton frequency ($f_{proton} \approx 2.27 \times 10^{23}$ Hz) and the macroscopic 136.1 Hz resonance through the discrete geometric structure of the Poincaré homology sphere $S^3/2I$. By modeling the binary icosahedral group as a cascading frequency divider with 12 stages, we demonstrate that 136.1 Hz emerges as a necessary geometric echo of the proton’s quantum oscillation — not a cultural artifact but a topological inevitability.

The paper bridges spectral geometry, harmonic analysis, and the Hilbert-Pólya conjecture in a manner that has not previously appeared in the literature. All predictions are falsifiable via cosmological topology measurements (Planck/future CMB missions) and proton charge radius refinements.

This manuscript has not been submitted elsewhere and all work is original.

Respectfully,

Rafael D. De Paz
