Dear Editorial Board,

I am formally submitting my manuscript entitled "**Scalable Topological Boundaries in Multi-Tier Hardware Architectures**" for consideration as a full-length research article in *ACM Transactions on Computer Systems*.

As abstract computing layers scale across public cloud grids, maintaining geometric system security against entropic variance and infinite loop execution remains a pivotal barrier. This paper constructs a novel "Multi-Tier Topological Continuum"—a formal algorithm categorizing logical bounds geometrically rather than strictly natively by API endpoints.

My arrays explicitly divide execution into 4 distinct physical states, strictly confining Byzantine inputs and volatile AI interactions to an outermost Tier 3, completely sealing Tier 0 immutable hardware roots. Using rigorous Turing limits and Shannon derivation laws, we mathematically map an orthogonal data diode model: executing logic exclusively bounds downwards while state adaptations execute upwards.

Because TOCS focuses explicitly on high-performance infrastructure, operating systems, and network isolation, I believe our physical bound model maps seamlessly to your editorial intent.

This work is entirely original, locally validated, and relies strictly on objective distributed logic derivations without introducing proprietary software stacks.

I look forward to your review of this topology matrix.

Sincerely,

Rafael D. De Paz
