Dear Editors,

I am writing to submit the enclosed manuscript, entitled

**“Free Will as Computational Necessity:
A Language-Theoretic and Concurrency-Control Proof
of Non-Deterministic Agency,”**

for consideration for publication in *Philosophy & Technology*.

Summary. The paper presents three independent formal proofs that non-deterministic agency (“free will”) is a computational requirement for any non-trivial dynamical system. Using Language-Theoretic Security (LangSec), thermodynamic entropy analysis, and Optimistic Concurrency Control (OCC), we establish that free will is necessary for informational novelty, necessary for thermodynamic sustainability, and compatible with global determinism.

Contributions.

- The *Novelty Requirement Theorem*: deterministic agents produce zero information-theoretic novelty ($I_{\text{novel}} = 0$).
- The *Entropy Injection Theorem*: free will is the only endogenous mechanism for local entropy reduction ($\Delta S < 0$).
- The *OCC Compatibility Theorem*: global consistency and local non-determinism are simultaneously achievable in distributed architectures.
- A formal definition of the “moral vector” $\vec{V} = \Delta I / \Delta S$ as a thermodynamic measure of ethical action.

Suggested Reviewers.

1. **Prof. Robert Kane** (UT Austin) — Leading authority on libertarian free will and the significance of indeterminacy.
2. **Prof. Daniel Dennett** (Tufts University) — Prominent compatibilist and philosopher of mind.
3. **Prof. Luciano Floridi** (Yale University) — Pioneer of the philosophy of informa-

tion and information ethics.

This manuscript has not been previously published and is not under consideration at any other journal. I confirm no conflicts of interest.

Respectfully submitted,

Rafael D. De Paz
